2 This Semester

▲□▶▲□▶▲□▶▲□▶ ▲□ ● ●

Problem Setting from Last Semester

• Consider a linear regression system:

$$\begin{cases} \phi_1^T \theta^* + N_1 = Y_1 \\ \phi_2^T \theta^* + N_2 = Y_2 \\ \dots \\ \phi_n^T \theta^* + N_n = Y_n \end{cases} \Phi^T \theta^* + N = Y$$

• The Least-Squares Estimate (LSE) of θ^* :

$$\hat{\theta} = (\Phi^{T} \Phi)^{-1} \Phi^{T} Y$$

• We aim to build non-asymptotic distribution-free confidence regions around the point estimate

< ロ > < 同 > < 回 > < 回 > < 回 > <

Main Idea of SPS[1]

• Find $\hat{\theta},$ the root of the normal equation:

$$0 = \sum_{t=1}^{n} \phi_t (Y_t - \phi_t^T \theta) = \sum_{t=1}^{n} \phi_t \phi_t^T (\theta^* - \theta) + \sum_{t=1}^{n} \phi_t N_t = H_0(\theta)$$

• Perturb the signs of the prediction errors:

$$H_i(\theta) = \sum_{t=1}^n \alpha_{i,t} \phi_t \phi_t^T(\theta^* - \theta) + \sum_{t=1}^n \alpha_{i,t} \phi_t N_t$$

 \bullet Order them in some measure and define a subset over which θ is accepted

Remark

If θ is "close" to θ^* , the prediction error is "close" to the noise term so with symmetrically distributed noise the perturbed ones' distribution should remain the same.

Outer Approximation

- To get regions that are easier to calculate: ellipsoidal outer approximation
- It leads to m-1 convex minimization problem and the qth largest optimum gives the proper radius of the ellipsoid in the parameter space $(p = 1 \frac{m}{q})$

Assumptions we would like to relax:

exogenous regressors (independent from the noise terms) symmetrically distributed noise scalar valued data \iff vector valued data

Scalar ARX Systems and Instrumental Variables

• Scalar ARX problem:

$$Y_t = \sum_{i=1}^{d_1} a_i^* Y_{t-i} + \sum_{i=1}^{d_2} b_i^* U_{t-i} + N_t \iff Y_t = \Phi_t^T \theta^* + N_t$$

- To handle the endogenous regressors instrumental variables (ψ_t):
 must be correlated with the regressors
 cannot be correlated with the noise terms
- How to generate IVs:
 - **1** use only previous inputs $(\psi_t = [U_{t-1}, U_t])$
 - 2 with least-squares estimation $(\psi_t = [\hat{Y}_t, U_t])$
- The IV-estimate:

$$\hat{\theta}_{IV} = (\Psi^T \Phi)^{-1} \Psi^T Y$$

IV-SPS for ARX Systems [4]

endogenous regressors, symmetrically distributed noise, scalar valued data

• Find $\hat{\theta}_{IV}$, the root of the normal equation:

$$0 = \sum_{t=1}^{n} \psi_t (Y_t - \phi_t^T \theta) = \sum_{t=1}^{n} \psi_t \phi_t^T (\theta^* - \theta) + \sum_{t=1}^{n} \psi_t N_t = H_0(\theta)$$

Perturb the signs of the prediction errors:

$$H_i(\theta) = \sum_{t=1}^n \alpha_{i,t} \psi_t \phi_t^T(\theta^* - \theta) + \sum_{t=1}^n \alpha_{i,t} \psi_t N_t$$

 \bullet Order them in some measure and define a subset over which θ is accepted

Performance of Different IV-Generating Methods

・ロ・・母・・母・・日・ のへの

IV-PEM for ARX Systems[2]

endogenous regressors, exchangeable noise, scalar valued data

• Find $\hat{\theta}_{IV}$, the root of the normal equation:

$$0 = \sum_{t=1}^{n} \psi_t (Y_t - \phi_t^T \theta) = \sum_{t=1}^{n} \psi_t \phi_t^T (\theta^* - \theta) + \sum_{t=1}^{n} \psi_t N_t = H_0(\theta)$$

• Permute the signs of the prediction errors:

$$H_i(\theta) = P_i \sum_{t=1}^n \psi_t \phi_t^T(\theta^* - \theta) + P_i \sum_{t=1}^n \psi_t N_t,$$

where P_i is a random permutation matrix

• Order them in some measure and define a subset over which $\boldsymbol{\theta}$ is accepted

Vector Valued ARX Systems and Instrumental Variables

Vector valued ARX problem
 (Y_t, U_t, N_t are vectors, A^{*}, B^{*} are matrices):

$$Y_t = \sum_{i=1}^{d_1} A_i^* Y_{t-i} + \sum_{i=1}^{d_2} B_i^* U_{t-i} + N_t \Longleftrightarrow Y = \Phi \Theta^* + N$$

The IV-estimate:

$$\hat{\Theta}_{IV} = (\Psi^T \Phi)^{-1} \Psi^T Y,$$

matrix valued!

▲圖 医 ▲ 国 医 ▲ 国 医 …

MIV-SPS [3]

endogenous regressors, symmetrically distributed noise, vector valued data

• Find $\hat{\Theta}_{IV}$, the root of the normal equation:

 $0 = \Psi^{\mathsf{T}}(Y - \Phi\Theta) = \Psi^{\mathsf{T}}\Phi(\Theta^* - \Theta) + \Psi^{\mathsf{T}}N = H_0(\Theta)$

• Perturb the signs of the prediction errors:

$$H_i(\Theta) = \Psi^T W_i \Phi(\Theta^* - \Theta) + \Psi^T W_i N,$$

where $W_i = \text{diag}(\alpha_i)$

 Order them in some measure (Frobenius-norm) and define a subset over which ⊖ is accepted
